

Assignment: Employee Class Implementation

Objective: Apply core OOP concepts including Encapsulation, Constructors, Static Variables, and Arrays of Objects.

Part 1: Create the Employee Class

Design a class named `Employee` containing the following members:

- **Private Fields:** `id` (int), `name` (string), `age` (int), and `salary` (int/double).
- **Static Variable:** `static int counter = 0;` (This should increment every time a new object is created).
- **Properties (Getters/Setters):** Provide access to read and write the private fields.
- **Constructors:**
 - Default Constructor: `Employee()`
 - Parameterized Constructor: `Employee(int id, string name, int age, int salary)`
- **Method:**
 - `Print()` : A method to display all the details of the employee.

Part 2: Main Method Implementation

In your `Main` method, test your class by completing the following tasks:

Task A: Single Object

1. Instantiate one employee:

```
Employee e1 = new Employee();
```

2. Read the employee's data from the user (console input) and assign it using properties/setters.
3. Call the `Print()` method to display the data.

Task B: Array of Objects

1. Create an array of 3 employees:

```
Employee[] employees = new Employee[3];
```

2. Initialize each element in the array (e.g., `employees[0] = new Employee();` etc.).

3. **Read Loop:** Use a `for` loop to ask the user to input the data for all 3 employees.
4. **Print Loop:** Use another `for` loop to call the `Print()` method for all 3 employees.
